

CAAA family communication flow in the recorded one-process simulation. Model states and scalar monitoring/validation diagnostics are transferred each round, together with two fixed whole-TRAIN climate strengths. Counts and two local sensitivity correlations are one-time uploads. Shared input scaling uses plain TRAIN count/sum/squared-sum vectors, with mean and SD broadcast. Target mean/SD and q80 are fitted locally; two float64 target summaries are exported for inverse decoding (16 bytes/client), and q80 is exposed in schema and evaluation diagnostics. These are recorded reporting exports. Full local training rows are not required for CAAA parameter updates. The selected primary coefficients are (1,0,0), making performance and climate aggregation terms inactive; the anchor experiments use (0.3,0.3,0.4). This is no secure-aggregation or differential-privacy implementation, and scalar/summary sharing can reveal information. Graph controls separately use privileged aligned TRAIN rainfall; centralized and static-router controls use declared raw-data pooling. The network and training equation are shown in 01_network.
